

Attack Surface and Hardening Report for `time_daemon.c` Scott Nguyen

1 Introduction

This report presents an analysis of the attack surface of a simple Linux daemon program written in C, `time_daemon.c`, which logs the current time to syslog every second. The daemon is launched at boot, detaches from the terminal, and gracefully terminates on signal. This report outlines the potential attack surfaces, their associated risks, and presents a hardened version of the daemon with security best practices in place.

2 Attack Surface Model

An attack surface is the total set of points where an unauthorized user could try to enter data into or extract data from a program. For `time_daemon`, the attack surface includes:

- **Signal Handling:** The daemon listens for `SIGTERM` and `SIGINT`. These signals can be sent externally, potentially allowing unauthorized shutdowns.
- **Environment Inheritance:** Any untrusted or malicious environment variables passed to the process could be misused internally or leak information.
- **Syslog Logging:** Unescaped or poorly formatted log messages may allow log injection.
- **File Descriptors:** The daemon closes `STDIN`, `STDOUT`, and `STDERR`, but may still inherit other file descriptors from the parent.
- **Privileges:** If the daemon starts as root, it retains root access throughout its execution, increasing risk in the event of compromise.
- **Resource Usage:** Unbounded resource use (e.g., memory, CPU) could degrade system performance or be exploited for denial-of-service.

3 Security Risks Identified

1. **Lack of Privilege Dropping:** The daemon did not previously drop root privileges after daemonization.
2. **Unsafe Signal Handling:** Use of `signal()` was non-portable and less secure.
3. **No Resource Limits:** There were no constraints on memory, file descriptors, or CPU usage.

4. **Insecure Logging:** Log messages were not verified or sanitized, potentially allowing log injection.
5. **Thread-Unsafe Time Conversion:** The use of `localtime()` was not thread-safe.
6. **No Umask Set:** The default umask could allow world-writable files to be created.

4 Hardened Implementation Summary

The following changes were implemented to reduce the daemon's attack surface:

- **Replaced `signal()` with `sigaction()`:** Provides safer and more predictable signal handling.
- **Dropped privileges after daemonization:** The process switches to the `nobody` user using `setuid(65534)`.
- **Set Resource Limits:** Memory and file descriptor usage are now capped using `setrlimit()` to prevent abuse.
- **Used `localtime_r()`:** The thread-safe alternative to `localtime()`.
- **Enabled safer logging:** Formatting logic ensures structured messages and prevents malformed entries.
- **Set restrictive umask:** Prevents created files from being world-readable or writable.

These changes ensure that the daemon is more resilient against both accidental misuse and targeted attacks, following secure coding best practices in embedded Linux environments.

5 Conclusion

By examining and reducing the attack surface of `time_daemon.c`, the system is now hardened against common threats like privilege misuse, uncontrolled signals, resource exhaustion, and logging vulnerabilities. This exercise demonstrates how even simple programs can be made significantly more secure with careful analysis and incremental improvements.
